PINON AND JUNIPER

A PRELIMINARY STUDY OF VOLUME, GROWTH AND YIELD

A. - FOREWORD

No previous detailed studies have been made to show how volume, growth and yield tables should be prepared for species represented in the coniferous woodland (pinon-juniper) stands of northern New Mexico and Arizona. Extreme variations in habit of growth make the problem a complicated one.

This study is based upon many individual trees occurring over a wide range of sites in various localities. While data were secured on a limited number of plots, which could not be expected to provide conclusive findings, nevertheless enough plots were taken to give a good indication of the range of conditions normally found.

Due to limited time, methods of statistical analysis were not used in all determinations. Statistical analysis was used occasionally to provide checks but these checks are not included in this bulletin.

Discrepancies will be found. Some are due to methods of handling data, while others resulted from wide variations encountered throughout the coniferous woodland stands. The all-aged character of woodland stands, as well as the varying species found thereon, prevents the use of conventional and standard methods of preparing yield tables.

Additional plots are needed in each of the woodland types before sufficient data are available to prepare satisfactory yield tables.

B. - INTRODUCTION

Pinon* (*Pinus edulis*, Engelmann) and one-seed juniper* (*Juniperus monosperma*, (Engelmann) Sargent) with a scattering of Rocky Mountain red cedar* (*Juniperus scopulorum*, Sargent) cover extensive areas in Colorado, Utah, New Mexico, and Arizona. Throughout their range, these species occupy more land area than the sawtimber forest types. Due to its occurrence near locations of settlement, the pinon and juniper type has been used in varying degrees of intensity to provide products for human use. The major products produced by this type are fuel, posts and pinon nuts. Under given market conditions, pinon is used for mine props and for narrow gauge railroad ties. When large enough, Rocky Mountain red cedar may be sawed into boards which are used for various special purposes.

Throughout the Southwest, products from the pinon-juniper type provide in varying degree a cash return to subsistence populations through the sale of posts, fuelwood and pinon nuts. For home consumption and for sale, the value of woodland products in the aggregate amounts annually to a considerable sum.

In some localities the past continuous drain has resulted in marked depletion. This depletion may be expressed in terms of dry or green fuelwood material with depletion of dry fuelwood most noticeable. Depletion of fence post material is more in evidence and covers extensive areas of the coniferous woodland type.

* The three species included in this study. There are several other species in the coniferous woodland type on which no data were gathered.

Cutting practices employed in removal of fence posts are far from conservative and from observations made it appears that indiscriminate cutting of smaller stems to reach material of post size has resulted in the loss of quantities of future fence post material which has taken a long time to produce. Also, the cutting of stems for fuel which, if left, would eventually make posts, has also contributed to depletion of post resources.

Beside the tangible values of wood products and pinon nuts may be noted the watershed protective values of this type, which is extremely important at higher elevations where the type approximates closed stand conditions.

Presumably the relative abundance of the woodland area, its use for range livestock - considered by many to be its most important value - and general lack of public and individual appreciation of the values of watershed protection, wood products and pinon nuts, has resulted in a general lack of appreciation of the true value of this type which has too often been expressed in terms of misuse.

This feeling that the coniferous woodland type is of minor importance is also reflected in the scarcity of literature regarding the species forming the type and absence of published material pertaining to volume, growth, and yield.

The pinon juniper stands lie between the sawtimber forests and the semi-desert grass lands either as a fringe or as isolated patches. In this study only that portion of the area covered by this coniferous woodland was examined which is located in Northwestern New Mexico and Northeastern Arizona. (See Figure 1.)

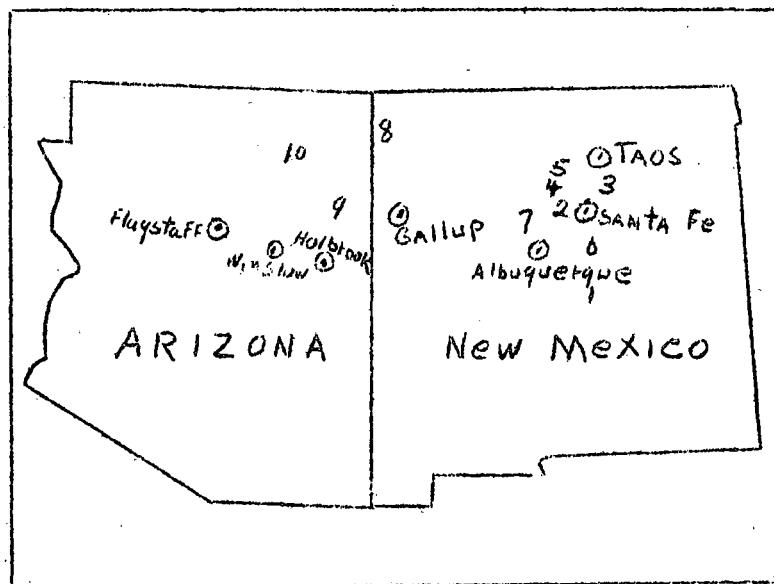

Figure 1. Distribution of Sample Plots.

1. Mountainair, New Mexico
2. Caja del Rio Grant, New Mexico
3. Sebastian Martin Grant, New Mexico

5. South Lobato Grant, New Mexico
6. San Pedro Grant, New Mexico
7. Espiritu Santo Grant, New Mexico
8. Cove, New Mexico
9. Pine Springs, Arizona
10. Forest Lake, Arizona

Woodland stands vary in form from scattered individuals or clumps of trees to dense stands. Variation in site condition is generally greater than in sawtimber stands. Seldom, if ever, are pure stands found covering large areas. This type is normally all-aged but occasionally exceptions occur as the relatively pure and even aged pinon stands that come in on favorable sites after clear cutting.

One-seed juniper stands are characterized by wide spaced many-stemmed trees, bushy crowns, low stature except on the better sites and many grassy openings. As one travels to higher elevations, more and more pinon occurs as a component of the stand with a corresponding decrease in the quantity of one-seed juniper. The pinon type is often composed of close set trees of narrow crowns and exhibits forest conditions with a closed crown canopy and litter and humus on the forest floor. With increase in elevation and a corresponding increase in moisture the grassy openings become fewer in number until they are largely relegated to the deeper soils as a fringe along the drainages.

Pure or relatively pure stands of Rocky Mountain red cedar are seldom found. This species usually occurs as isolated trees or as groups of trees in mixture with one-seed juniper, pinon, oaks and ponderosa pine at higher elevations in the pinon-juniper type. Relatively pure stands may appear on deeper soils as a narrow fringe along drainage-ways with trees of all ages present.

C. - DEFINITIONS

1. Acre. 43,560 square feet measure on a horizontal projection of the ground surface.

2. Age. Total age of the tree based upon a stump count and corrected for years to reach a height of one foot. Average age to one foot.

Pinon, 9 years
One-seed juniper, 13 years
Rocky Mountain red cedar, 8 years

3. Average diameter. Average diameter at breast height or at one foot of an entire stand or part of a stand computed by dividing the total basal area of the trees by their number and converting the quotient to diameter either inside or outside the bark.

4. Basal area. The cross sectional area in square feet at one foot or at breast height where B.H. measurements are used, outside or inside bark.

5. Breast height. A point of measurement on the main stem located 4.5 feet above the average ground level.

6. Branches. Those stems originating above or below stump height which form separate units.

7. Brush volume. All the green and dry brush (branches) suitable for use in soil and moisture conservation operations, i.e., all limb material not included in cubic volume.

8. Crown density. The amount of space occupied by the crowns as expressed in per cent. Determined by summing up all crown spread in square feet on a unit area and then dividing by the number of square feet in the unit area.

9. Crown length. The distance in feet from the tip of the tree to the lowest green branch.

10. Crown spread. The average width of a tree crown as determined from two diametrically opposite measurements from one extreme branch tip to the other. Sometimes referred to as crown width. It may also mean the area in square feet as determined from average crown width which may be used to determine crown density.
11. Cord. The standard cord of 4x4x8 feet.
12. Cut trees. Trees that have been cut but originally formed a part of the stand.
13. Dominant classes. The Swedish System was used in this study. The fourteen classes used in field measurements (See Appendix) were reduced to six, as follows:
 - a. Dominant. The largest, tallest and most vigorous trees in the stand. In some stands the dominant trees may be decadent due to age.
 - b. Co-dominant. Usually well developed trees reaching into the main canopy. If not widely spaced, there is some pressure on the sides of the crowns. Some of these may later become dominant.
 - c. Intermediate. Trees of inferior development. Considerable side pressure if in closed or partially closed stands. Some may, through release, develop into co-dominants or dominants.
 - d. Suppressed. Trees that are distinctly inferior. These may, through release, develop into one of the three classes noted above.
 - e. Dead. Dead standing trees.
 - f. Reproduction. All trees less than 4.5 feet tall.

14. Fence posts. For the junipers only. Standard line posts 7 feet long and 5 inches top diameter outside bark, or the equivalent of 20 square inches for split posts. While this will give the maximum yield of standard line posts, actual yield will be somewhat lower due to hidden defect and difficulties of splitting.
15. Height. The total height of the tallest stem from the average ground level to the tip of this stem.
16. Mean annual increment. The average annual volume growth of the tree from the year of origin to the age under consideration.
17. Main stem. The tallest stem or branch of the tree or clump.
18. Normal or fully stocked stand. A stand that utilizes its site to the fullest extent allowed by soil and moisture conditions. Density will, therefore, vary widely. The crown canopy need not be closed or complete. Maximum stocking is not implied although it may occur in some localities.
19. Number of trees per acre.
 - a. Total. All trees on an acre regardless of size.
 - b. Partial. All trees above four and one-half feet in height.
 - c. Reproduction. All trees less than four and one-half feet in height. These were recorded by height classes.
20. Partially cut trees. Trees from which green or dry branches or stems have been harvested for fuel or fence posts.
21. Partial stand. Those trees above 4.5 feet in height or trees sufficiently large to produce wood products as fuel, posts, etc.
22. Pieces. Sticks four feet long and two inches or more in diameter at the middle, outside bark.

23. Poles. Straight stems at least eight feet long having specified minimum top diameters. Suitable for mine props, ties, corral poles, etc.
24. Periodic annual increment. Average annual volume growth within a given age interval; in this study 10 years.
25. Site index. Basal area in square feet of all trees over 4.5 feet in height, in terms of an average diameter outside bark for the partial stand of five inches at one foot above the average ground level. Example: When the "site index" is "50", it means that when the average diameter of the partial stand is five inches, the stand will have a basal area of 50 square feet.
26. Site quality. The site quality of a woodland area is its relative productive capacity as determined by climate, soil and other factors. Only three site classes are suggested at this time.
27. Stocking. The degree to which the productivity of an area is utilized by the existing forest stand.
28. Stump height. All trees in this study were cut and measured at a point one foot above the average ground level.
29. Tree. Single or multiple stemmed. Example: In one-seed juniper many stems start at below or above the ground surface or from a short primary bole. The entire clump is considered to be one tree.
30. Volume table. Tables showing the estimated volumes of trees of various sizes, expressed in cubic feet or other standards of measurement.

31. Woodland. Woodland as used in this report refers to pinon-juniper stands. Only 3 species (*J. monosperma*, *J. scopulorum* and *P. edulis*) were included in this study.

D. - BASIC DATA

Standards of measurement and forms on which data were recorded are noted in the appendix.

1. Plots. The data used in the preparation of volume tables and other findings noted in this report were secured by five investigators working in localities in Arizona and New Mexico noted in Figure 1.

Trees in the plots established were selected to represent the range of diameters, heights and form most typical of the woodland stands encountered. Thirty-nine plots were taken. Each plot was so located as to contain about 200 trees over 4.5 feet in height. Data and the manner in which it was to be procured were based upon a working plan. The distribution of the thirty-nine plots by area and by types follows:

Table 1. Size of Study Plots by Types*

Area of Plots Acre	Number of Plots by Type			
	All Plots	Juniper Type	Pinon Type	Pinon-Juniper Type
Less than 0.5	13	3	4	7
0.5 to 0.99	14	5	5	3
1.0 to 1.49	9	4	4	1
1.5 to 1.99	2	2	0	0
Over 2.0	1	1	0	0
Total	39	15	13	11
Average Size Acres	0.800	1.061	0.688	0.509

* See Section G -"Composition of Woodland Stands" for basis of type determinations.

The total area covered by plots was 30.609 acres. The smallest plot was 0.20 acre and the largest 3.705 acres.

None of the plots were rejected for abnormality since not enough plots were taken on which to base definite conclusions in this respect. Limited funds, together with the time necessary to gather data on each plot, limited the scope of the study in terms of the number of plots that could be taken.

2. Field Measurements and Forms. Study plots were laid out with a Forest Service compass and steel tape. Individual tree measurements were recorded on Form PSP1 for each tree over 4.5 feet in height. All measurements were made with a steel tape or graduated rod. Reproduction was recorded by species in terms of three height classes. On the reverse side of the form, general information concerning the plot was entered.

Twenty-five trees were selected at random for cutting on each plot. These were distributed among the three species and by diameter at one foot and height classes. Additional trees of exceptional size were taken where time permitted. Form VS 1-38 was filled in for each tree in accordance with the definitions of terms under standards of field measurement as noted in the appendix.

3. Office Computations. Wherever possible, statistical methods of analysis were used. Due, however, to extreme range in variation, as well as lack of time to fully analyze data by this means, it was often necessary to resort to graphic methods.

E. - VOLUME TABLES

Volume tables in terms of cubic volume were prepared using different groups of measurements to determine those most suitable and reliable for use in predicting volume. Converting factors for cord volume were also ascertained. For pinon, diameter at breast height and number of four-foot pieces were found to give the best results; for one-seed juniper and Rocky Mountain red cedar, diameter of the tallest stem at one foot and crown diameter. These volume tables have already been issued and will be found in Regional Bulletin No. 59, Woodland Series No. 8 including Supplement No. I. For these volume tables the aggregate deviations were readily reduced to less than two per cent; however, it would be difficult to reduce the average percentage deviations below 50 per cent for the junipers noted or 25 per cent for pinon without undue manipulation and adjustment.

The cubic volume in the tables includes that contained in sticks four feet long and two inches or more in diameter, outside bark, at the center. The volume of each stick was computed by Huber's formula. Bark is included but the stump excluded from these volumes. The preliminary alignment chart was constructed after the methods of Bruce and Reinecke; however, subsequent adjustments were made by graphic methods.

These tables are regional tables. They should be corrected for local use by standard methods. Actual measured volume should be obtained for at least 100 trees due to the wide variation in volume found. Comparison of a local and the regional curve is noted in Figure 2.

Other volume tables are included (Figures 3, 4 and 5). These present cubic and brush volumes for the three species. Figuring a certain percentage of the brush to be removed for use in erosion control operations, one could decide to remove, for example, one-tenth of the brush volume and construct a curve covering this amount applying from an extensive cruise the diameter classes tallied to determine the quantity of brush available.

Tables 2, 3 and 4 are self-explanatory and present some interesting averages as well as other useful data.

F. - GROWTH

Growth is slow in the coniferous woodland type with but little variation in growth rate for individual trees between good and poor sites due to the all-aged character of coniferous woodland stands. Bands of wide and narrow rings are not uncommon but the variation is not large. Age is but relative in the three species as false rings are common and are identified in the field only with difficulty. Unfortunately, time was not available to make a study of false rings so they were not determined and were disregarded in the determination of age.

The all-aged nature of coniferous woodland stands prohibits the use of age in site determinations and in yield table construction. The tables and figures that are presented in this portion of the bulletin are based on all plots and trees. Local corrections may be necessary to provide usable data.

The following data applies to individual trees. Growth is maintained at a relatively even rate until the tree is 500 or more years old unless some adverse factor obtains. As the trees become older, they achieve sufficient dominance to receive some side light which probably accounts for maintenance of growth rate for an extremely long period of time (See Figure 6.)

It will be noticed that Rocky Mountain red cedar has the greatest preliminary diameter growth rate and the lowest terminal growth rate of any of the three species. The diameter, at one foot, growth rate increases rapidly until about the fortieth year, when having attained a rate of increase of 0.78 inch per decade it begins to decrease, falling

below the growth of pinon at about the 150th year and one-seed juniper in the 180th year. Pinon has an intermediate growth rate to the 140th year after which it exceeds both the junipers until the 250th year. At that point, it falls below the curve for one-seed juniper until the 350th year after which it regains ascendancy.

One-seed juniper is the slowest but has the most uniform diameter growth rate of the three species. Its diameter growth rate reaches a peak of 0.58 inch per decade at about the 60th year, then falls slowly until the 170th year after which the rate of diameter growth falls but 0.04 inch in over 300 years.

Diameter at one foot attained throughout the life of individual trees is relatively the same for all species with Rocky Mountain red cedar the only one showing any decided slowing down with age.

Total height growth is maintained throughout life, although for pinon and Rocky Mountain red cedar there is a slowing of height growth after the first fifty years. (See Figures 7, 8 and 9.)

One-seed juniper has an entirely different tendency. At first, height growth is relatively fast. It then decreases for about 250 years, after which there is another period of accelerated growth. The reasons underlying this condition have not been determined.

Tables 5, 6 and 7 are interesting, particularly when one compares mean annual and periodic annual increment.

The following discussion applies to stand conditions: Instead of using total age as a basis for growth, diameter at one foot was substituted due to the all-aged nature of the stands. For all practical purposes, diameter at one foot inside bark is linear. Total height varies somewhat between species. For one-seed juniper, height growth is rapid until the tree is 3 inches in diameter. After that, growth is greatly reduced and nearly linear.

For Rocky Mountain red cedar, the most rapid height growth is attained prior to the time this species attains a stump diameter of one inch. After this period, growth diminishes until a diameter of about five inches is reached, at which time a period of accelerated growth starts that continues until a diameter of about 18 inches is attained.

For pinon, height growth is much slower than for Rocky Mountain red cedar but is maintained for a longer period.

These relationships are illustrated in Figures 10, 11, 12 and 13.

Growth rate in per cent based on basal area at one foot is greatest for Rocky Mountain red cedar and lowest for one-seed juniper until the individual tree attains a size of about $1\frac{1}{4}$ inches in diameter at one foot. At this point, pinon exceeds Rocky Mountain red cedar and at 16 inches one-seed juniper. From then on, pinon maintains an almost even rate of growth while one-seed juniper has only a slightly diminishing rate of growth after reaching a size of $1\frac{1}{4}$ inches at the stump. The rate of growth of Rocky Mountain red cedar decreases more rapidly than the other species, terminating at a diameter of 25 inches with a

rate of 0.1 per cent. These relationships can be seen in figure 14.

All growth is gross as no attempt was made to determine net growth or net growth rates.

G. - COMPOSITION OF WOODLAND STANDS

An analysis of the 39 plots constituting the basic data for this study shows the following average composition based on basal area at stump height for trees over 4.5 foot high.

Table 11.

Composition of 39 Plots by Basal Area at Stump Height.

Species	Per cent
Pinon	49.3
One-seed juniper	46.8
Rocky Mt. red cedar	3.4
Ponderosa pine	0.3
Gambel oak	0.2
Total	100.0%

Through trial using 60 per cent of the basal area for trees over 4.5 high as a basis for type determinations, plot distribution by types appears as follows:

1. 15 Plots in the juniper type.
2. 13 Plots in the pinon type.
3. 11 Plots in the pinon-juniper type.

From the standpoint of available data, it is believed that a percentage of 60 should form the basis for type delineations for those

species. Using 80 per cent as a basis gave relatively few plots in the pinon or juniper type, most of the plots falling in the combined pinon-juniper type.

H. - DISTRIBUTION BY TREE CLASSES

All green living trees were recorded as to dominance and by age groupings as over-mature, mature, immature, and reproduction. These are relative classes as determined by field examination. Records were kept of the number of dead trees, trees that had been cut and trees partially cut. The following data does give a good picture of distribution based on dominance. See Table 12 for composition of Woodland Types by Tree Classes and Number of Trees Per Acre.

1. Dominants. An average of eight dominants, all species, were found per acre constituting 2 per cent of the total living trees. Some of the largest junipers could only be classed as intermediate due to their position in the crown canopy. Some plots had no dominant trees while others had as many as forty per acre. For all plots 45 per cent of the dominants were juniper and 55 per cent pinon, the percentage varying by types.

2. Co-Dominants. An average of 32 co-dominants, all species, were found per acre constituting about 8 per cent of the stand. All plots were found to have trees in this class ranging from 3 to as high as 115 per acre. More were found in the pinon type than in other types. Forty per cent of the co-dominants were junipers and 60 per cent pinon. This class had less members in the pinon-juniper type or 4.5 per cent of the total stand.

3. Intermediates. This class represented the bulk of the trees, averaging 334 per acre of all species. As many as 1108 intermediates per acre were found in the mixed type. Junipers constituted 38 per cent of this class and pinon 62 per cent. In terms of numbers of trees intermediates made up 82 per cent of the average stand over 4.5 feet in height.

4. Suppressed. This class represented 8 per cent of the live trees, averaging 32 per acre. All plots contained some trees in this class, one plot having 155 trees per acre or over 10 per cent of the stand. Apparently junipers are less subject to suppression in mixed stands than pinon since of the total number 65 per cent were pinon and 35 per cent juniper.

5. Reproduction. While three height classes were applied in collecting field data, they were consolidated for this report. Of the total stand, reproduction constituted about 35 per cent of the total living trees or about 250 per acre, all species. Variations per acre ran from 10 in an open juniper stand to 1140 in a pinon type of greater than average density. Thirty per cent of the reproduction was juniper and 70 per cent pinon.

Where the plots are segregated by types it is found that the 15 juniper plots have 37 per cent juniper and 63 per cent pinon reproduction. The mixed type has 33 per cent and the pinon type 21 per cent juniper reproduction.

The juniper plots contained the fewest seedlings, 135 per acre.

The mixed type had the largest average number of seedlings per acre, or 353. The pinon type averaged 295 per acre. As would be expected, the juniper type supports the fewest seedlings, 31% of all trees. Reproduction constitutes forty per cent of all trees in the pinon type.

6. Mortality. A tally was kept of all standing dead trees found on each plot. For all plots and species there was an average of 23 dead trees per acre. Of this average, 7 or 30 per cent were one-seed juniper and 16 or 70 per cent were pinon. Variations in number of dead trees from none to 115 per acre were found. Given similar stand conditions the number of dead trees present is naturally an index to the degree of use.

7. Cutting. Sample plots were selected in those portions of the coniferous woodland stands where past and present cutting has been at a minimum. However, all but six plots gave evidence of past cutting of entire trees or portions thereto.

For all plots there was an average of 17 cut trees per acre, half pinon and half juniper. Located in an area of heavy use, one plot showed 75 trees cut per acre.

8. Total Stand. The composite stand for the 39 plots averaged about 700 trees per acre of which 36 per cent were reproduction, 2 per cent cut and removed, 3 per cent dead; the remaining 59 per cent representing the living stand over 4.5 feet in height. The three types show considerable departure from the average. The pinon type averages about 735 trees per acre. The mixed type 980 and the juniper type 460 trees per acre.

Table 13 presents a comparison of stand composition by types, basal area, number of trees and cubic volume.

I. - SITE INDEX

Coniferous woodland stands of the Southwest are usually composed of two or more species of trees and are all aged, which precludes the use of conventional methods of determining site index or site quality based on age and height of dominants. Therefore, site determinations were based on basal area at one foot when the stand above 4.5 feet high averages five inches one foot above the average ground level. The small number of plots on which this study is based only permits preliminary findings.

The site classifications as shown by Figure 17, while tentative, fit the basic data for the 39 plots remarkably well. Eleven plots fall in Site Quality I, fifteen in Site II and thirteen in Site III. While distribution by diameters at one foot is poor, the groupings are satisfactory for the small number of plots.

Crown cover expressed in per cent may be used to determine site but is not as good as the basal area method previously noted. The basis is the amount of space that the crowns of trees over 4.5 feet high occupy. In dense stands, crown cover will exceed 100 per cent due to the various crown levels present. The curves presented in Figure 18 should be used with discretion. For rough work they should prove satisfactory.

Figure 19 gives yield per acre in cords, using the site classification first noted. These curves are less satisfactory than the crown density curves and are subject to the same limitations of use.

Use of this material would be as follows:

Determine crown density.

Determine site.

Determine yield in cords per acre.

Using the composite type crown density is 0.6 or 60 per cent.

The average site index is 74. The yield in cords is 11.7 cords per acre.

The site is average for the composite type.

Another expression of crown density may be used as noted by tables 14, 15 and 16, which are based on crown density expressed in per cent.

Table 14 is based partly on rocky mountain red cedar, but the preponderant number of trees used in the preparation of this table were one-seed junipers.

As would be expected, more pinon trees are required per acre than juniper to have the same degree of crown density. The reverse is true for cubic or cord volumes.

Previous mention has been made that site classification by the basal area method is best. Determination of site by crown density is hardly practical but is included to show interesting relationships.

J. - YIELD

While many sites and conditions were sampled, the number of samples obtained do not allow too accurate an evaluation of yield. However, this is the best preliminary data available at present.

The yield data presented were based on trees over 4.5 feet in height and on diameter outside bark at one foot. Yield tables have been prepared by types and by species.

The curves for number of trees per acre are of the usual form for all-aged stands except there are fewer trees in the one inch class than would ordinarily be expected. Thus the curves for pinon, one-seed juniper and all species fall sharply from the numbers indicated in the two-inch diameter class. The reason for this is that many one inch trees were below 4.5 feet in height, and consequently were tallied as reproduction.

Rocky Mountain red cedar does not exhibit this tendency as it grows rapidly in the juvenile stage. Thus more stems in the one-inch class are recorded. However, in open stands, Rocky Mountain red cedar tends to assume the growth habits of one-seed juniper.

The yields in cords and solid cubic feet have been computed by types, by species for types and for a composite of all types. Gross annual yield per acre indicates the quantity of wood produced yearly which may be harvested without stand depletion.

The gross growth rate of all species and all types is approximately 1.3 per cent. For one-seed juniper it is 1.0 per cent, for Rocky Mountain red cedar 1.1 per cent and for pinon 1.5 per cent.

Table 17.

Yield Table for All Plots and All Species

Per Acre

Dia. 1 ft. inches	Age Years	No. of trees	Basal Area Sq.ft.	Cubic Volume cu.ft.	Cords	Brush Volume cu.ft.

K. - MISCELLANEOUS DATA

1. Quantity of Heart wood. In Table 37 are noted the percentages of heart wood and sap wood for Rocky Mountain red cedar and one-seed juniper. Rocky Mountain red cedar is slower to form heart wood at first but produces a maximum amount of heart wood in a shorter period of time.
2. Decay. Decay impairs the strength and durability of juniper and pinon and reduces the yield of fence posts. Pinon appears to be relatively free from decay, none being found in trees with stump diameters less than 10 inches. The incidence is low, 4.0 per cent and the quantity negligible. One-seed juniper appears to be the most defective of the three species since trees above 4.0 inches at one foot are subject to decay. The incidence is 21.4 per cent and quantity 3.3 per cent of the gross volume. The incidence of decay for Rocky Mountain red cedar is almost as great as for one-seed juniper but no decay was found in trees having a stump diameter of less than 9.0 inches. See Table 38.
3. Volume-Basal Area Ratio. The one-seed juniper type produces less cord wood per square foot of basal area than either the pinon or mixed types. The pinon type produces the most wood while the mixed type is intermediate.
4. Volume - Crown Spread Ratio. In the mixed type a greater crown density is required to produce a unit of usable wood than in the other two types. The one-seed juniper type requires the least crown density to produce a unit of usable wood.
5. Posts and Poles. Posts and poles should be tallied in cruising as stands are so variable that frequency tables would usually be valueless.

Freezing injury to arbor vitae and junipers in
Kansas.
Am. Jour. of Botany, 20:593-5.
6. 1921- Miller, F. H.
Reclamation of grasslands by Utah juniper on the
Tusayan National Forest, Arizona.
Journal of Forestry, 19:647-51.
7. 1921- Pack, D. A.
After ripening and germination of *Juniperus* seeds.
Botanical Gazette, 71:31-60; and 70:139-150.
8. 1910- Phillips, F. J.
The dissemination of junipers by birds.
Forestry Quarterly, 8:60-73.
9. 1912- Phillips, F. J. and W. Mulford.
Utah juniper in central Arizona.
U.S.D.A. Circular, 197.
10. 1915- Sudworth, G. B.
The cypress and juniper trees of the Rocky
Mountain Region.
U.S.D.A. Bulletin 207.
11. 1934- Geographical junipers.
Horticulture, 12:266-7.

- APPENDIX -

STANDARDS OF FIELD MEASUREMENT

1. Diameter. A steel diameter tape was used to measure diameters. Recorded in inches and tenths.
2. Bark Thickness. Two measurements of bark thickness were taken with a steel tape or steel rule on freshly cut surfaces. Recorded as double bark thickness in inches and tenths.
3. Heights. A graduated rod was used for short trees and an Abney hand level for tall trees. Recorded in feet and tenths.
4. Lengths. A graduated rod or steel tape was used. Recorded in feet and tenths.
5. Crown diameter. Two diametrically opposite measurements were taken with a steel tape. Recorded in feet and tenths.
6. Crown length. A graduated rod or steel tape was used. Recorded in feet and tenths.
7. Sections. A graduated rod or steel tape was used. Recorded in feet or tenths. A permissible deviation of 0.2 foot was allowed for four foot lengths.
8. Stump height. Stump height is considered to be one foot above the average ground level.
9. Breast height. A point 4.5 feet above the average ground level.
10. Plots. Plots were laid out by means of a staff compass and steel tape. Error of closure to be not greater than 1 in 500. Plots to contain not less than 200 trees; to be 2 to 3 times longer than broad and so laid out as to cut across the topography.

11. Tree Classes - Recorded by class number.

a. Dominant.

1. Overmature, over topping, decadent, unthrifty.
2. Mature, overtopping, thrifty
3. Immature, overtopping, thrifty.

b. Co-dominant

4. Overmature, not overtopping, decadent, unthrifty.
5. Mature, not overtopping, thrifty
6. Immature, not overtopping, thrifty

c. Intermediate

7. Overmature, unthrifty, $1/2$ to $2/3$ the height of dominants
8. Mature, thrifty, $1/2$ to $2/3$ the height of dominants.
9. Immature, thrifty, $1/2$ to $2/3$ the height of dominants.

d. Suppressed

10. Decadent, unthrifty, less than $1/2$ the height of dominants
11. Mature, unthrifty, less than $1/2$ the height of dominants
12. Immature, unthrifty, less than $1/2$ the height of dominants

e. 13. Dead

f. 14. Reproduction Height Classes

1. 0 to 1 foot
2. 1 to $3\frac{1}{2}$ feet
3. $3\frac{1}{2}$ to $4\frac{1}{2}$ feet

12. Posts and Poles.

- a. Posts, round. Seven feet long, minimum top diameter of 5 inches outside bark.

b. Posts, split Twenty square inches of top surface.

5" top - one round post

7" top - two split posts

8.5" top - three split posts

10" top - four split posts

11" top - five split posts.

c. Poles

<u>Length</u>	<u>Minimum top diameter</u>
8 feet	6 inches
10 "	6 "
15 "	5 "
20 "	5 "
25 "	4 "

13. Symbols

PP - Ponderosa pine

DF - Douglas fir

PE - Pinon

JS - Rocky Mountain red cedar

JM - One-seed juniper

OM - Oaks

14. Growth studies. A well graduated scale was used. Growth rings were counted from the outside in by decades on the average radius and measurements made from the center out. Data recorded in inches and twentieths. The first measurement from the center, together with the number of rings in the fractional decade, was recorded.

15. Cord. Outside measurements of 4 x 4 x 8 feet. Measured with steel tape and recorded in cubic feet.
16. Brush. Brush was piled, the dimensions of the pile measured with a steel tape and the contents recorded in cubic feet.
17. Defect. Recorded as to type, location and size.
18. Sapwood. Average width was measured and the number of growth rings determined.
